

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

## INTRODUCTION TO ARTILLERY CIRCULAR M, REVISED.

---

This circular contains complete ballistic tables with which may be computed the values of the quantities pertaining to the motion of a projectile when sufficient data are given to make the problem mathematically determinate. The fundamental hypothesis upon which they are based is that the ratio of the retardations of any two *different* projectiles moving at the *same speed is independent of the velocity*, assuming air conditions, as barometer, wind, etc., the same. Then, taking as standard the retardation of some particular projectile, the retardation of any other projectile may be found by dividing the standard value by a constant. This constant is called the ballistic coefficient and is denoted by  $C$ . The ratio of the retardation of a (nonstandard shaped) projectile to that of one of the same weight and diameter but standard shape is called the coefficient of form. Assuming the fundamental hypothesis to be correct, the chief problems of exterior ballistics are three:

(1) To find experimentally the retardation,  $R$ , of the standard projectile as a function of the projectile's velocity.

(2) To compute tables with the data given by (1), from which may be found any desired ballistic quantity, as range, time of flight, etc., knowing a sufficient number of the other variables to make the problem determinate.

(3) To determine, by theory and experiment combined, the best value of  $C$  to use for each projectile under any conditions of firing. Owing to the inaccuracy of our original hypothesis, to the variations in air density caused by changes in temperature and barometer and by change of altitude, and to the insufficiency of our mathematical methods (which necessitate the introduction of an integrating factor) this ballistic coefficient  $C$  is very difficult to determine. The same projectile will have different values of  $C$  for different trajectories if computations are to agree with measurements.

The experimental firings upon which our tables are based were made by Krupp at Meppen in 1881. From these firings Gen. Mayevski formulated laws of air resistance, which were later extended by Col. Zaboudski to higher velocities. These laws, reduced to English units by Col. Ingalls, are expressed by the following equations, in which  $R$  is the retardation of the standard projectile in feet

per second.  $R$  divided by the proper  $C$  gives the retardation,  $r$ , of any other projectile:

$$R = Cr = (7.6090480 - 10)v^{1.55}, \quad 3,600 > v > 2,600f.s.$$

$$R = Cr = (7.0961978 - 10)v^{1.7}, \quad 2,600 > v > 1,800f.s.$$

$$R = Cr = (6.1192596 - 10)v^2, \quad 1,800 > v > 1,370f.s.$$

$$R = Cr = (2.9809023 - 10)v^3, \quad 1,370 > v > 1,230f.s.$$

$$R = Cr = (6.8018712 - 20)v^5, \quad 1,230 > v > 970f.s.$$

$$R = Cr = (2.7734430 - 10)v^3, \quad 970 > v > 790f.s.$$

$$R = Cr = (5.6698914 - 10)v^2, \quad 790 > v > 0f.s.$$

Col. Siacci succeeded in reducing these discontinuous functions to the following empirical formula (reduced to English units by Col. Ingalls), which gives the retardation for any velocity within the above limits:

$$R = Cr = \left\{ 0.284746 v - 224.221 + \sqrt{(0.234396 v - 223.754)^2 + 209.043 + \frac{0.019161 v(v - 984.261)}{371 + \left(\frac{v}{656.174}\right)^{10}}} \right\} \times 0.896$$

When 0.896 is taken as the coefficient of form of Siacci's projectile compared to Mayevski's, this single formula gives results for the entire range of velocities up to 3,600 foot-seconds that check well with experiment and with Mayevski's discontinuous formulæ.

The tables first used by United States Artillery officers were computed by Col. Ingalls in 1884 from a discussion of Bashforth's coefficients, which were based on experiments made in England between 1865 and 1880 with projectiles now long obsolete. The present tables take as standard a projectile of about three calibers length with an ogival head of radius two calibers. Just as Bashforth's projectiles were superseded by Mayevski's 2-caliber ogive projectiles, so are the latter being replaced by long-pointed and boat-tailed projectiles, the radii of whose ogives are seven calibers or more. Consequently, judging from the replacement of tables based on Bashforth's coefficients by these based on Mayevski's formulæ, the time is ripe for a new series of experiments and new tables based thereon. The present revision of the tables was made in 1917 under the direction of the Ordnance Board at the Sandy Hook Proving Grounds.

TABLE I.

TABLE I was computed by Col. Ingalls from his formulas based upon the Krupp firings already referred to. It gives the values of the space, altitude, inclination, and time functions with the velocity (real or pseudo) as the argument. The table extends from 3,600 to 100 foot-seconds, with intervals so small as to admit of accurate interpolation with first differences only, except for the altitude and inclination functions in the latter part of the table where second differences are necessary for accurate work. These functions were computed by the formulas given on pages 245-247 of Col. Ingall's Handbook of Problems in Exterior Ballistics (Artillery Circular N), using seven decimal logarithms, thereby insuring the correctness of the last figure.

The space function  $S$  tabulated opposite a velocity  $V$  is the actual distance in feet that would have been traversed by the standard projectile while its speed fell from 3,600 foot-seconds to  $V$  foot-seconds if it had been projected horizontally with an initial velocity of 3,600 foot-seconds and *if its path had remained horizontal throughout*. The deviation of the path from the horizontal is allowed for by making use of Siacci's pseudo velocity  $u$  in entering the table instead of the actual velocity  $V$ . The other functions are similarly computed for special conditions and applied to practical cases by the use of proper formulæ. Their derivation and use are fully described in Artillery Circular N, and most standard works on exterior ballistics.

TABLE II.

TABLE I is sufficient for the accurate solution of the most important problems of gunnery. But some of the solutions with Table I are indirect and tentative, and therefore very laborious. To obviate this, TABLE II was computed from Table I by Col. Ingalls in order to present the necessary information in a form suitable for rapid solution of practical problems. It consists of 50 separate tables computed for as many different muzzle velocities, ranging from 825 to 3,600 foot-seconds. In them are tabulated the so-called secondary functions against the space function as argument. Since two functions, velocity and one other, must be known to enter Table II, it is called a double-entry table and unless the increments of velocity between the component tables are small so that calculations for intermediate values need seldom be made, the labor of using it is very large. These secondary functions, first suggested by Braccialini in 1883, were developed by Col. Ingalls and by him brought to a high degree of practical usefulness. Ingall's tables were first published in Supplement to Artillery Circular F in 1893.

After many years of service rendered by this table, however, some of his original functions have proved to be seldom useful and several changes have appeared desirable. Therefore, in this new edition five of the functions originally tabulated have been omitted and two new ones inserted. For the benefit of those familiar with the old tables the following résumé of the changes and the reasons therefor is presented.

$Z$  has been extended to 20,000 in all tables and one decimal place has been added to  $u$  and logarithm  $B'$  in tables for  $V > 1,300$  in order to meet the present needs more fully. The four tables for  $V = 3,300, 3,400, 3,500,$  and  $3,600$  foot-seconds, computed by C. A. Junken and published in supplement to the old Circular M, are included and five new ones have been computed for  $V = 2,050, 2,150, 2,250, 2,350,$  and  $2,450$  foot-seconds. These additional tables facilitate calculations with the higher velocities now in use.

$A', A''$  have been replaced by a new function  $II$ , suggested by Col. Hamilton, Coast Artillery Corps, which was computed from Ingalls' values of  $A'$ . This simplifies the computation of the maximum ordinate and danger range. Logarithm  $C'$  is omitted and its functions are served by the new function logarithm  $Q$ . The advantage of the substitution is that  $Q$  is a more slowly changing function of  $V$  and hence its use facilitates interpolation for odd velocities.

The  $B$  function, being easily found from the relation  $B = AB'$  and being seldom used, is omitted.  $D'$  is also left out because it relates to a drift formula now obsolete. The table is arranged so that the fewest possible pages have to be turned in making computations for any one gun. The intervals of velocity between tables are made small to minimize cross interpolation. With this end in view also the most slowly varying functions obtainable have been tabulated. For example, logarithm  $Q$  was tabulated in preference to  $Q$  itself.

#### TABLE IIA.

This is a new table computed by Col. Hamilton, assuming air resistance proportional to the square of the velocity and taking the same air resistance ratio chosen by Col. Ingalls for the first part of the old Table II for the range  $V = 0$  to  $V = 825$  feet per second.

$$Cr = [5.669891 - 10] v^2$$

It is intended to replace the first part of the old Table II and all of the old Tables III and IV. The functions tabulated in it are, in so far as practicable, the same as in Table II, thus reducing the necessary formulæ to a minimum. The only practical use of muzzle velocities below 800 foot-seconds at the present time is to secure a high angle of fall at moderate ranges. The table is therefore especially intended for high-angle fire.

## TABLES III TO X.

TABLE III gives the ratio of air density under standard conditions ( $\delta_1$ ) to that under any other conditions of temperature and pressure ( $\delta$ ). This ratio,  $\frac{\delta_1}{\delta}$ , enters as a factor in the value of  $C$ , it being assumed to represent the ratio of the retardations experienced by the same projectile under actual and standard atmospheric conditions, respectively. As a matter of fact, the variation of sound velocity with air temperature causes a change in the shape of the air-resistance curve, so that the ratio of retardations for the two conditions of the atmosphere depends somewhat on the velocity of the projectile.

TABLE IV gives the function  $D_w$  for computing wind deflections for initial velocities from 0 to 3,600 foot-seconds.

TABLE V enables the penetration of Krupp cemented armor by capped projectiles to be calculated. An example will best show its use:

To find the penetration of a vertical plate of K. C. armor by the 14-inch capped projectile at 12,000 yards:

The range table for this gun (M. V. = 2,250 foot-seconds) gives  $V_w = 1,604$  foot-seconds at 12,000 yards. From Table V,  $P_v = 1.18$ .

$W = 1,660$  pounds and  $d = 14$  inches. Hence  $\frac{t}{d} = (1.18) \frac{1660}{(14)^3} = 0.918$ ,

whence  $t = 14 (0.918) = 12.8$  inches penetration at normal impact. The angle of incidence is  $\omega = 10.6^\circ$ , whence 1 per cent must be subtracted from the normal impact perforation. Therefore, the projectile is able to just pierce a plate 12.7 inches thick. This does not mean, however, that it would penetrate 12 inches into a 15-inch plate, as the thicker plate would probably shatter the projectile.

TABLE VI gives the probable value of the coefficient of form of ogival headed projectiles computed on the theory (derived from experiments) that the retardation of projectiles of the same weight and diameter is proportioned to the mean sine of the angle between the tangent to the ogive and the axis.

TABLE VII gives the empirical relation derived by Col. Hamilton connecting powder temperature and muzzle velocity. It may be applied to velocities outside the range given (2,000–2,500) with good results.

TABLE VIII is a probability table which is useful in all problems of accuracy of fire if the mean error of the gun is known. The width of the 50 per cent zone is 1.69 times the mean (numerical average) error and is defined as the width of a zone of indefinite length (whose sides are right lines equally spaced on either side of the center of impact) that may be expected to contain one-half of all the points of impact.

TABLE IX gives the curvature of the earth for ranges up to 36,000 yards. The correction to range on this account is small, and with the flattest trajectories does not exceed 1 per cent. For example, consider the 2,400-pound 16-inch projectile and suppose the muzzle velocity is 2,700 foot-seconds. The following table summarizes the results:

Range on a plane. . . . . yards..	11, 000	19, 000	26, 000	45, 000
Increase in range due to curvature of earth. yards..	80	111	123	142
	° /	° /	° /	° /
Approximate angle of fall. . . . .	6 0	13 24	21 32	46 50
Decrease in $\omega$ due to curvature of earth. . . . .	6	10	14	22

TABLE X gives data for determining the altitude factor,  $f_a$ . This table is due to Col. Hamilton. The mean height must be used in entering this table to find the value of  $f_a$  for any complete trajectory. For flat trajectories the mean height is two-thirds of the maximum. The approximate mean height  $h$ , considered as a function of the length of arc, is given by the following table taken from Hamilton's article in Journal United States Artillery, vol. 24, No. 1.

$\frac{1}{2}(\phi^\circ + \omega^\circ)$	$\frac{h}{y_0}$	$\frac{1}{2}(\phi^\circ + \omega^\circ)$	$\frac{h}{y_0}$
°		°	
1	0.667	50	0.625
10	.665	60	.600
20	.661	70	.567
30	.654	80	.528
40	.642	90	.500

These values were computed for the quadratic law of air resistance.

#### THE BALLISTIC COEFFICIENT.

The complete expression for  $C$  is:

$$C = \frac{\delta_1}{\delta} f_w f_a \frac{w}{\beta i d^2}$$

Considering the factors in turn:

$\frac{w}{d^2} = C_0$ , = weight of the projectile divided by the square of its diameter, evidently measures the power of the projectile to cleave the air. This is the fundamental factor of  $C$ , the others being merely corrections to take account of abnormal conditions.

$\frac{\delta_1}{\delta}$ , = ratio of normal to actual air density at the gun, is given in Table III. This is taken as the inverse ratio of the retardations

experienced by the moving projectile under normal and actual atmospheric conditions, respectively.

$f_w = 1 \pm \frac{2 W_x T^3/4}{X}$ , is the wind factor which corrects for a wind component of  $W_x$  miles per hour in the plane of fire. The credit for this convenient method of wind range correction is due to Col. Hamilton. The sign to be used in the expression is determined by the consideration that for a helping wind  $f_w > 1$  and for an opposing wind  $< 1$ . This factor allows for the probable increase of wind velocity with altitude. For very flat trajectories ( $y_0 < 200$  feet) a better expression is  $f_w = 1 \pm \frac{3 W_x T}{X}$ .

$f_a$  is the altitude factor, which allows for the reduction of air density at the mean height of the trajectory below the density at the gun (Table X). The correction may be very considerable in high-angle firing.

$\beta = \sqrt{\sec. \phi}$  is the integrating factor which is intended to compensate for the error introduced by the approximation involved in Siacci's method. This error comes from the assumption that  $\frac{\cos. n-2\phi}{\cos. n-1\phi}$  ( $n$  is Mayevski's exponent) is unity, which is made in integration. This error is negligible when  $\phi < 10^\circ$ , considering the other inaccuracies present, but becomes appreciable at greater angles. The best value of  $\beta$  to use is different according to whether it is desired to compute  $X$ ,  $T$ ,  $y_0$ , or some other function with precision, so that a compromise must be made and the choice of  $\sqrt{\sec. \phi}$  as the best value is based on a comprehensive view of the situation.

$i$  is the coefficient of form (Table VI) which corrects for a departure of the form of the projectile from the standard shape. This factor has been denoted by  $c$ , but is here called  $i$  to prevent confusion with  $C$  and also to conform to the usage of the Navy. The application of air-resistance laws derived from experiments on one form of projectile to the calculation of the flight of another form is but an approximation and hence the departure of  $i$  for service projectiles from unity indicates the degree of obsolescence of the tables. For modern (1916) long-pointed projectiles the coefficient of form is about 0.6.

Another factor is sometimes put in the denominator of the expression for  $C$ , called the "reducing factor," which is intended to allow for the deviation of the axis of the projectile from the tangent to the trajectory and for varying ratios of  $d^3$  to  $w$ . It is really a factor to reconcile theory with observation and may be omitted in the absence of experimental data. It is denoted by  $\gamma$ .

DEFINITIONS OF SYMBOLS.

$w$  = weight of projectile in pounds.

$d$  = diameter of projectile in inches.

$g$  = acceleration due to gravity, taken as 32.16 feet per second.<sup>2</sup>

$C_o = \frac{w}{d^2}$  = uncorrected ballistic coefficient in weight per unit of projected area.

$\beta, i, \frac{\delta_1}{\delta}, f_a, f_w$  are numerical factors each normally equal to unity which are used to correct  $C_o$  for abnormal conditions. They are discussed in the preceding paragraphs.

$C = f_a f_w \frac{\delta_1}{\delta} \frac{C_o}{i\beta}$  = corrected ballistic coefficient.

$\epsilon$  = angle of position or angle of site.

$W_x$  = wind component in plane of fire in miles per hour.

$W_z$  = wind component across plane of fire in miles per hour.

$\phi$  = angle of departure.

$\phi$  = angle of elevation + angle of jump.

$\theta$  = angle of inclination of the tangent to the trajectory to the horizontal (+ on the ascent, - on the descent).

$\omega$  = absolute value of angle of fall.

$x$  = horizontal distance in feet.

$y$  = vertical distance or altitude in feet.

$t$  = time in seconds.

$v$  = velocity in feet per second.

$V$  = initial velocity in feet per second.

$u$  = pseudo velocity in feet per second, is of such magnitude that if laid off on a line parallel to the initial velocity  $V$ , its horizontal projection equals the horizontal projection of the actual velocity  $v$ .

$z, = \frac{x}{C},$  = horizontal range in feet for the standard projectile ( $C=1$ ) is the argument of Table II.

$S_u, A_u, I_u,$  and  $T_u$  or  $S(u), A(u),$  etc., are the space, altitude, inclination and time functions (primary functions) of Table I.

$A, H, B', U, T',$  and  $Q$  are the secondary functions of Table II for the particular initial velocity  $V$  and value of  $Z$  under which they are tabulated, which are defined by the succeeding formulas.

$\frac{AV^2}{700^2}, H, B', \frac{V}{u}, N, Q,$  and  $\frac{x_o}{X}$  are the corresponding functions of

Table IIA, which are similarly defined hereafter.

In general, characteristics of the point of fall are distinguished by capital letters, as  $X, V_o, T,$  etc., and characteristics of the summit by the subscript  $o$ , as  $x_o, y_o, v_o,$  etc.

## BALLISTIC COEFFICIENT FORMULAS.

$$C_o = \frac{w}{d^2} \quad (1)$$

$$C = \frac{\delta_1}{\delta} f_w f_a \frac{C_o}{\beta^2} \quad (2)$$

$$\beta = \sqrt{\sec \varphi} \quad (3)$$

$$f_w = 1 \pm \frac{2 W_x T^5 / 4}{X} \quad (+ \text{ with favorable wind, } - \text{ with opposing wind}) \quad (4)$$

$$\log. f_a = y_o \times 10^{-5} \text{ (approximate)} \quad (5)$$

## FORMULAS TO BE USED WITH TABLE I.

$$x = C (S_u - S_v) \quad (6)$$

$$\frac{y}{x} = \tan. \varphi - \frac{C}{2 \cos.^2 \varphi} \left[ \left( \frac{A_u - A_v}{S_u - S_v} \right) - I_v \right] \quad (7)$$

$$\tan. \theta = \tan. \varphi - \frac{C}{2 \cos.^2 \varphi} (I_u - I_v) \quad (8)$$

$$t = C \sec. \varphi (T_u - T_v) \quad (9)$$

$$v = u \cos. \varphi \sec. \theta \quad (10)$$

$$y_o = 4.05 T^2 \text{ (approximate)} \quad (11)$$

## FORMULAS TO BE USED WITH TABLE IIA.

$$x = Cz \quad (12)$$

$$A = \left( \frac{700}{V} \right)^2 \left( \frac{AV^2}{700^2} \right) \quad (13)$$

$$\sin. 2\varphi = AC \quad (14)$$

$$\tan. \omega = B' \tan. \varphi, \log. B' = \log. \left( \frac{\tan \omega}{\tan \varphi} \right) \quad (15)$$

$$y_o = HX \tan. \varphi \quad (16)$$

$$\log. u = \log. V - \log. \frac{V}{u} \quad (17)$$

$$v = u \cos. \varphi \sec. \theta \quad (10)$$

$$t = \frac{C z N \sec. \varphi}{V} = \frac{Nx \sec. \varphi}{V} \quad (18)$$

$$Q = \frac{V^2 \sin. 2\varphi}{gX} \quad (19)$$

$$x_o = \left( \frac{x_o}{X} \right) X \quad (20)$$

$$y = \frac{\tan. \varphi}{A} (A - a)x \quad (21)$$

$$\tan. \theta = \frac{\tan. \varphi}{A} [A - a(1 + b')] \quad (22)$$

### DIFFERENTIAL FORMULAS.

The change of initial velocity caused by a small variation in weight of projectile for a fixed powder charge is given by—

$$\frac{\Delta V}{V} = -m \frac{\Delta w}{w} . . . . . (27)$$

The quantity  $m$  lies between 0.20 and 0.40 for service conditions, the average value being 0.30. If  $m$  were 0.5 the muzzle energy would be unchanged by a small change in  $w$ .

For computations where  $V < 825$  foot-seconds (Table IIA) the following formula (Hamilton's) gives the variations of range caused by small changes in  $V$ ,  $\varphi$  and  $C$ :

$$\frac{\Delta X}{X} = 2L \frac{\Delta V}{V} + (L \cot \varphi - \frac{1+L}{2} \tan \varphi) \frac{\Delta \varphi}{3438} + (1-L) \frac{\Delta C}{C}. \quad (28)$$

$$\text{where } L = \frac{1}{B'} = \frac{\tan \varphi}{\tan \omega} \quad (29)$$

In (28),  $\Delta\varphi$  should be taken in *minutes*.

For example, take the case of the 4'7 Panama howitzer,  $M. V. = 800$  foot-seconds,  $w = 60$  pounds. At a range of 2,500 yards, we have  $C = 2.679$ ,  $\varphi = 12^\circ 25'$ , whence  $Z = \frac{X}{C} = 2,800$ , and  $\text{colog. } L = \log. B' = 0.0379$ ,  $L = 0.9164$ . What will be the change in range, when  $V = 815$ ,  $\varphi = 12^\circ 30'$ ? We have:

$$\frac{\Delta V}{X} = +15, \Delta \varphi = +5', \Delta C = 0.$$

$$\frac{\Delta X}{X} = 2(.916) \frac{15}{800} + \left( \frac{0.9164}{0.2202} - \frac{1.9164}{2} (0.2202) \right) \frac{5}{3438} + 0,$$

and  $\Delta X = (2,500) (0.0344 + 0.00575) = 86 + 14.4 = 100$  yards increase. The change due to the increase of 5 min. in  $\varphi$  caused an increase in range of 14.4 yards. The range table gives  $\varphi$  for 2,600 yards as  $13^\circ 0'$ , hence the expected increase in range due to 5 minutes increase of  $\varphi$  is  $\frac{5'}{35'} (100) = \frac{100}{7} = 14.3$  yards, agreeing with the 14.4 yards found above.

When  $V > 825$  foot-seconds (Table II) (28) should be replaced by the following Ingalls' formula:

$$\frac{\Delta X}{X} = -L \frac{\Delta A_v}{A} + \frac{L}{1719} \frac{\Delta \varphi}{\tan 2\varphi} + (1-L) \frac{\Delta C}{C} \quad . \quad . \quad . \quad (30)$$

Here  $L$  is given by (29),  $\Delta A_v$  is the increment in  $A$  caused by a change of  $\Delta V$  in  $V$ ,  $\Delta \varphi$  as in (28) is the increment of  $\varphi$  in minutes of arc, and  $\frac{\Delta C}{C}$  is the per cent change in  $C$  caused by atmospheric conditions or change in weight of projectile.

For example, take the 14-inch gun, M. V. 2,250 foot-seconds,  $w=1,660$  pounds,  $C=13.444$ .

When  $X=12,000$  yards,  $\varphi=8^\circ 27' 6$ , and  $Z=\frac{X}{C}=2,680$ .

In Table II for  $V=2,250$ ,  $Z=2,680$ , we find  $A=0.02162$  and  $\log B'=0.10005$ , whence  $L=0.7942$ . If the M. V. were reduced to 2,220 foot-seconds and the weight of projectile to 1,600 pounds, how much increase in  $\varphi$  would have to be made to get the same range? We have  $\Delta X=0$ ,  $\frac{\Delta C}{C}=\frac{60}{1,660}$ . From Table II,  $V=2,200$  foot-seconds, we find  $A=0.02267$  for  $Z=2,680$ , so that if  $\Delta V$  were  $-50$  foot-seconds,  $\Delta A_v$  would be  $0.02267-0.02162=+0.00105$ . Therefore, for  $\Delta V=-30$ ,  $\Delta A_v=3/5 (0.00105)=+0.00063$ . Substituting in (29)—

$$0 = -0.794 \left( \frac{63}{2,162} \right) + \frac{0.794 \Delta \varphi}{1719 \tan 16^\circ 55' .2} - (1-0.7942) \frac{60}{1,660}$$

$$0.00152 \Delta \varphi = 0.0231 + 0.0074 \text{ and}$$

$$\Delta \varphi = \frac{0.0305}{0.00152} = 20' .1 \text{ increase.—Answer.}$$

#### *Height of target.*

To find the angle of departure  $\varphi$  necessary to hit a point situated at an angle of  $\epsilon^\circ$  above the horizontal through the gun, the following formulas (due to Col. Ingalls) should be used:

$$\sin (2\varphi - \epsilon) = \sin \epsilon (1 + \cot \epsilon \sin 2\varphi_x) \quad . \quad . \quad . \quad . \quad . \quad (31)$$

$\varphi_x$  is the angle of departure necessary to hit a point vertically below the target, on the level of the gun. Knowing the range to the target, one computes  $\varphi_x$  in the usual manner, then substitutes the values of  $\varphi_x$  and  $\epsilon$  in (31) and solves for  $\varphi$ .

#### EXAMPLES OF THE USE OF THE TABLES.

1. To find the quantities usually tabulated in a range table for a given gun: The first step in computing a range table is to determine  $C$  for standard atmospheric conditions as a function of the range, from actual firings.

This  $C = \frac{wf_a}{\beta_i d^2}$ , and is the complete ballistic coefficient for standard conditions, since  $\frac{\delta_1}{\delta}$  and  $f_w$  are then unity.

Take the 6-inch gun, M. V. = 2,600 foot-seconds, firing a 108-pound long-pointed projectile.

We will take  $C=4.894$  and calculate the quantities pertaining to a range of 10,000 yards. Ordinarily 5-place logarithms would be used, but a slide rule will be used in these computations. The steps in the work are as follows:

$$\text{Compute from (12), } Z = \frac{X}{C} = \frac{3(10,000)}{4.894} = 6130.$$

In Table II for  $V=2,600$ ,  $Z=6,130$ , find the secondary functions:

$$A = 0.05212$$

$$U = 1,198.1$$

and

$$H = 0.32326$$

$$T' = 3.557$$

$$B' = 1.6776$$

$$\log. B' = 0.22468$$

$$\log. Q = 0.25219$$

$$L = \frac{1}{B'} = 0.5961$$

The angle of departure is given by (14):

$$\sin 2 \varphi = (0.05212) (4.8940) = 0.2551, \text{ whence } \varphi = 7^\circ 23'.$$

The characteristics of the point of fall are given by—

$$(15) \tan \omega = B' \tan \varphi = 1.6776 \tan 7^\circ 23' = 0.2174 \text{ whence } \omega = 12^\circ 16' = \text{angle of fall.}$$

$$(10) V_\omega = U \cos \varphi \sec. \omega = (1,198.1) (0.9917) (1.0234) = 1,215 \text{ foot-seconds} = \text{striking velocity.}$$

$$(23) T = CT' \sec. \varphi = (4.8940) (3.557) (1.0084) = 17.55 \text{ secs.} = \text{time of flight.}$$

The maximum ordinate is given by (16):

$$y_0 = HX \tan \varphi = (0.32326) (30,000) (0.1296) = 1,257 \text{ feet.}$$

The drift is given by (24):

$$\text{Taking } K = 0.75, \text{ drift} = 0.25 \frac{(6)^3}{108(25)} (7^\circ 4' + 12^\circ 3') (1.008) = 0^\circ 4' \text{ or}$$

$$(0.4) \left( \frac{\pi}{180} \right) 10,000 = 70 \text{ yards to the right.}$$

The danger space for a target 20 feet high is given by (25):

$$\Delta X = \frac{20}{.2174} \left( 1 + \frac{20}{0.217(30,000)} \right) = 92.0 (1.003) = 92.2 \text{ feet} = 30.7 \text{ yards.}$$

Therefore, if the gun were aimed at the water line of a vertical target 20 feet high an "over" in range of not more than 31 yards would be permissible.

To compute the errors in range caused by variation of the elements of fire use (30):

$$\frac{\Delta X}{X} = -L \frac{\Delta A_v}{A} + \frac{L}{1719} \frac{\Delta \varphi}{\tan 2\varphi} + (1-L) \frac{\Delta C}{C} \quad (30)$$

To find  $\Delta A_v$ , look in Table II:  $V=2,500$  and  $V=2,700$ . Find the two  $A$ 's for  $Z=6,130$ , and subtract from the  $A$  already found for  $V=2,600$ , obtaining the change in  $A$  caused by a change of 100 foot-seconds in  $V$ .

For  $V=2,500$  we find  $A=0.05671$  and for  $V=2,700$ ,  $A=0.04803$ .

Hence if  $\Delta V = +100$ ,  $\Delta A = 0.4803 - 0.05212 = -0.00409$  and if  $\Delta V = -100$ ,  $\Delta A = 0.05671 - 0.05212 = +0.00459$ .

Therefore the mean value of  $\frac{\Delta A_v}{A}$  is  $-\frac{0.00433}{0.05212} \frac{\Delta V}{100} = -0.000831 \Delta V$ .

Substituting known values in (30):

$$\frac{\Delta X}{X} = -0.596(-0.000831 \Delta V) + \frac{0.596}{1,719 \tan 14^\circ 46'} \frac{\Delta \phi}{C} + (1 - 0.5961) \frac{\Delta C}{C}.$$

$$\frac{\Delta X}{X} = +0.00050 \Delta V + 0.00132 \Delta \phi + 0.404 \frac{\Delta C}{C}$$

In words, at a range of 10,000 yards:

An increase of 10 foot-seconds in  $V$  would cause an increase in range of 0.50 per cent or 50 yards.

An increase of 10 minutes in  $\phi$  would cause an increase in range of 1.32 per cent or 132 yards.

An increase of 1 per cent in  $C$  would cause an increase in range of 0.404 per cent or 40.4 yards.

The effect of wind may be found from (4) and (26).

From (4), with a 10-mile component in the plane of fire:

$$f_w = 1 \pm \frac{2(10)(17.55)^{5/4}}{30,000} = 1 + 0.0240$$

Therefore a 10-mile head wind would cause a decrease in  $C$  of 2.40 per cent and a corresponding decrease in range of  $(40.4) \times 2.40 = 97$  yards.

From (26) the deflection produced by a 10-mile wind at right angles to the plane of fire is:

$$\frac{10 D_w}{(2,600) (0.9917)} (6, 130) = 23.8 D_w$$

In Table IV for  $V = 2,600$ ,  $Z = 6,130$ , we find  $D_w = 0.0070^\circ$ , so that the wind deflection for a 10-mile cross wind blowing to the left is  $(23.8) (0.0070) = 0.167^\circ$  left.

2. A second typical problem is to compute the value of  $C$  from actual firing records. Take the following data obtained at the Sandy Hook Proving Grounds in firing a special projectile with a wind shield of nine calibers ogive in the 12-inch gun.

Elevation =  $15^\circ 0'$ .

$V = 2,469$  foot-seconds.

Jump, estimated, =  $-5'$ .

$T = 35.23$  seconds.

Range = 19,887 yards.

Wt. of shell = 900 pounds.

These are the mean results for five rounds fired on the same day. To find  $C$  one proceeds as follows:

Compute  $Q$  from formula (19).

$$Q = \frac{(2,469)^2 \sin 29^\circ 50'}{(32.16) (3) (19,887)} = 1.5805, \log. Q = 0.19880.$$

In Table II, for  $V=2,450$  and  $V=2,500$  find the  $Z$  corresponding to this value of  $\log Q$ . Result:

$$V=2,450, Z=4,918.$$

$$V=2,500, Z=4,943.$$

Whence, by interpolation,  $Z$  (for  $V=2,469$ ) is 4,927.

$C$  is then given by (12) and is equal to  $\frac{X}{Z} = \frac{3(19,887)}{4,927} = 12.11$ .

For this  $Z$ ,  $T'=2.772$ . Hence the theoretical time of flight is

$$T = CT' \text{ sec. } \varphi = (12.11) (2.772) (1.0349) = 34.73 \text{ secs.}$$

The next step is to analyze this value of  $C$  and compare the value of  $i$  with the theoretical value given in Table V.

The observed atmospheric conditions at the time of firing were:

Barometer, 30''.15.

Temperature, 49° F.

Wind 20 miles per hour, blowing from a point 30° to the right of the plane of fire.

In Table III for  $\text{bar.} = 30''.15$ ,  $t = 49^\circ$ ,  $\frac{\delta_1}{\delta}$  is found to be 0.961.

$$\text{From (4) } f_w = 1 - \frac{2(20 \cos 30^\circ) (35.23)^{5/4}}{3(19,887)} = 0.950.$$

$$\text{Hence the range table value of } C \text{ should be } \frac{12.11}{(0.950) (0.961)} = 13.26.$$

To obtain the value of  $i$  this value must be divided by  $\frac{\beta}{f_a} \left( \frac{w}{d^2} \right)$ .

The maximum ordinate of the trajectory is found from (16).

In Table II, for  $V=2,469$ ,  $Z=4,927$ , we find  $H=0.30777$ .

Hence  $y_0 = (0.30777) (3) (19,887) (\tan 14^\circ 55') = 4,890$  feet.

Here  $\frac{1}{2} (\varphi + \omega) = \frac{1}{2} (15^\circ + 22^\circ) = 18^\circ 5'$ , hence the mean height of the trajectory is  $0.662 y_0$  or 3,240 feet. In Table X, for  $h=3,240$  feet,  $f_a$  is found to be 1.102.

$$\beta = \sqrt{\text{sec. } \varphi} = 1.017 \text{ from (3).}$$

$$\text{Hence } \frac{w}{i d^2} = \left( \frac{13.26}{1.102} \right) (1.017) = 12.24 \text{ and}$$

$$i = \frac{900}{12.24(12)^2} = 0.51 = \text{coefficient of form.}$$

Table VI gives  $i=0.46$ . The principal error in this computation of  $i$  from experiment lies in the values of  $f_a$  and  $f_w$ , since the condition of the upper atmosphere is unknown. The value of  $f_a$  is for average surface temperature and the wind is assumed to be in the same direction at all altitudes and of a velocity increasing with the height. If  $i$  had been taken as 0.46, and the other factors as before, and the range computed, the error in range would have been about 680 yards.

3. Computation of the range from theoretical considerations alone; for a given muzzle velocity, projectile, and angle of departure.

Take as example the 12-inch gun and assume  $V=2,361$  foot-seconds,  $\varphi=12^\circ 23'$ .

First compute  $C$  from (2) taking  $\frac{\delta_1}{\delta}$  and  $f_w$  as unity. The weight of projectile is 1,070 pounds and the value of  $i$  is 0.63.

$$C = f_a \frac{1,070}{(0.63) (144) \sqrt{\sec. 12^\circ 23'}} = 11.58 f_a.$$

$f_a$  is unknown until  $y_o$  is found, so a process of successive approximation must be used:

$$\text{Compute } A = \frac{\sin 2\varphi}{C} = \frac{\sin 24^\circ 46'}{11.58} = 0.03618. \quad \text{In Table II for}$$

$$V=2,350, A=0.03618, \text{ we find } Z=4,212.$$

$$V=2,400, A=0.03618, \text{ we find } Z=4,345.$$

and so for  $V=2,361$ ,  $A=0.03618$ ,  $Z$  is 4,241.

For  $Z=4,241$ ,  $V=2,361$ ,  $H$  is 0.2993.

$X = CZ = (11.58) (4,241) = 49,100$  feet and  $y_o = HX \tan \varphi$ ,  
 $= (0.2993) (49,100) \tan 12^\circ 23' = 3,228$  feet, whence  $f_a$  corresponding to  $h=0.663 y_o=2,140$  feet, is 1.066.

Therefore the corrected value of  $C$  is  $(11.58) (1.066) = 12.35$ .

Repeating the process with this new value of  $C$ :

$A = \frac{0.03618}{1.066} = 0.03393$  and  $Z$  for this value of  $A$  (and  $V=2,361$ ) is  $Z=4,055$ . Hence  $X=4,055 (12.35) = 50,080$  feet = 16,693 yards.  $H$  for  $Z=4,055$ ,  $V=2,361$ , is 0.2969.

Therefore corrected  $y_o = (0.2969) (50,080) \tan 12^\circ 23' = 3,266$  feet; mean height  $= h = 0.663 (3,266) = 2,166$  feet, and  $f_a = 1.067$ .

A third computation could be carried through. In practice, of course, one estimates  $f_a$  beforehand and usually the estimation is close enough to the computed value to make the second approximation exact.

Twenty-six rounds were fired at the proving grounds in September, 1917, with a quadrant elevation of  $12^\circ 28'$ . The jump was approximately - 5 min. The mean of the ranges corrected individually for atmospheric conditions and variations in muzzle velocity was 16,670 yards, only 23 yards less than the computed range.

4. If it is desired to find the height of a projectile above the ground at any distance from the gun, formulas (21) and (22) are to be used. For example, suppose it is desired to compute ordinates 500 yards apart for a 2,000 yards trajectory of the United States magazine rifle and to locate the summit, given  $V=2,700$  foot-seconds,  $C=0.3894$ .

$$Z = \frac{X}{C} = \frac{6,000}{0.3894} = 15,410.$$

For the intermediate points at 500, 1,000, and 1,500 yards, the  $z$ 's are  $\frac{1}{4}$ ,  $\frac{1}{2}$ , and  $\frac{3}{4}$  of  $Z$ , respectively. In Table II,  $V=2,700$  foot-seconds, find  $a$ , corresponding to each  $Z$ . Results:

$z=3,852$	$a=0.02378$
$z=7,705$	$a=0.07202$
$z=11,557$	$a=0.15971$
$Z=15,410$	$A=0.28947$

From (14),  $\sin 2\varphi = AC = (0.28947)(0.3894) = 0.1127$ , and  
 $\phi = 3^\circ 14'$ .

Therefore  $\tan \varphi = 0.05649$ , and substituting in (21)—

$$y = \frac{\tan \varphi}{A} (A - a)x = \frac{0.05649}{0.28947} (0.28947 - a)x.$$

To find the height at any distance  $x$ , substitute numerical values for  $a$  and  $x$ , finding:

$x=1,500$	$y=77.8$ feet.
$x=3,000$	$y=127.4$ feet.
$x=4,500$	$y=114.0$ feet.
$X=6,000$	$Y=0$ feet.

The coordinates of the summit may be found as follows:

Look up  $H$  corresponding to  $Z$  and use (16). We find  $H$  (for  $V=2,700$ ,  $Z=15,410$ ) to be 0.38855. Hence

$$y_s = (0.38855)(6,000)(0.05649) = 131.7 \text{ feet.}$$

The distance to the summit could be found theoretically from (21) by substituting this known value of  $y_s$  and solving for  $x_s$  by trial and error. But practically this formula gives so flat a maximum that  $x$  can not be found accurately by its use. Therefore recourse must be had to (22). At the summit  $\tan \theta = 0$ , so (22) reduces to

$$A = a_s (1 + b_s') = 0.28947.$$

Try  $z_s = 9,000$ . Then  $a_s = 0.09690$  and  $\log b_s' = 0.29069$ ; hence

$$a_s (1 + b_s') = 0.09690 (1 + 1.9530) = 2.8614.$$

If  $z_s = 9,100$ ,  $a_s = 0.09902$ , and  $b_s' = 1.9580$ , whence

$$a_s (1 + b_s') = 0.09902(2.9580) = 2.9290.$$

Interpolating, true  $z_s = 9,000 + \frac{333}{676}(100) = 9,049$ .

Therefore  $x_s = Cz_s = (0.3894)(9,049) = 3,526$  feet or 1,175 yards.

5. To hit a point situated above or below the gun, the usual method is to compute the angle of departure for a horizontal range equal to the distance to the target and then add to this the angle of position. But this is only an approximation. The exact method of computing

the elements of a trajectory to hit a point not on a level with the gun is illustrated by the following problem:

It is desired to hit an observation balloon, distant horizontally 5,000 yards and 1,000 feet high, with the 6-inch howitzer. What angle of elevation should be employed? This howitzer fires a shell weighing 90 pounds and the muzzle velocity of the outer zone is 1,150 foot-seconds.

The range table gives  $\varphi = 16^\circ 16'$  and  $C = 1.856$  for a range of 5,000 yards in the outer zone. Hence  $\varphi_x = 16^\circ 16'$  and  $\sin 2\varphi_x = 0.5378$ .

Also  $\tan \epsilon = \frac{1,000}{15,000} = 0.06667$ ; hence  $\epsilon = 3^\circ 49'$  and  $\sin \epsilon = 0.06656$ .

Substituting in (31)

$$\begin{aligned}\sin (2\varphi - \epsilon) &= \sin \epsilon (1 + \cot \epsilon \sin 2\varphi_x) \\ &= 0.06656 \left(1 + \frac{0.5378}{0.0667}\right) = 0.6031\end{aligned}$$

so that  $2\varphi - 3^\circ 49' = 37^\circ 5'$  and  $\varphi = 20^\circ 27' =$  proper elevation of the howitzer. Adding  $\varphi_x$  and  $\epsilon$  gives  $20^\circ 5'$ , so that the error involved in the approximate method is  $22'$ .

The characteristics of the point of fall are readily found by (14), (22), (10), and (23).

$$\text{From (14), } A = \frac{\sin. 2\phi}{C} = \frac{\sin. 40^\circ 54'}{1.856} = 0.3530.$$

$$\text{At the target, } z = \frac{x}{c} = \frac{15,000}{1.856} = 8,080.$$

In Table II, for  $V = 1,150$ ,  $z = 8,080$ :

$$a = 0.29005, \log. b' = 0.12462, u = 725.6, t' = 9.147.$$

Therefore:

$$(22) \quad \tan. \theta = \frac{0.3729}{0.3530} (0.3530 - 0.2900 (1 + 1.3324))$$

$$= -0.3416, \text{ so that } \theta = -18^\circ 52' = \text{striking angle.}$$

$$(10) \quad v = (725.6) (0.9370) (1.0568) = 719 \text{ foot-seconds} = \text{striking velocity.}$$

$$(23) \quad t = 1.856 (9.147) (1.0673) = 18.13 \text{ seconds.}$$

A check is given by (21):

$$y = \frac{0.3729}{0.3530} (0.3530 - 0.2900) (15,000) = 998 \text{ feet} = \text{height of target.}$$

Actually  $C$  in this example should have been corrected to agree with the range table value for  $\phi = 20^\circ 27'$ , but this merely requires a repetition of the computation of both  $\phi_x$  and  $\phi$  using the new  $C$ , and is not instructive.

6. The use of Table IIA (for velocities below 825 foot-seconds) is precisely similar to that of Table II (for velocities above 825 foot-seconds). Consider this problem:

The enemy is transporting supplies along a road protected by a low hill whose reverse slope is known to be  $30^\circ$ . It is desired to shell the road, using 90-pound H. E. shell in the 6-inch howitzer. What is the shortest range at which the battery can reach the objective?

For the inner (fourth) zone the velocity given by the service charge is 550 foot-seconds. The range-table value of  $C$  is known to be approximately 2. As a first attempt, estimate  $\phi$  to be  $25^\circ$ .

$$\text{Then } A = \frac{\sin. 2\phi}{C} = \frac{0.7660}{2} = 0.3830.$$

$$\text{To enter Table IIA, compute } \frac{AV^2}{700^2} = 0.3830 \left( \frac{550}{700} \right)^2 = 0.2362.$$

In Table IIA, the corresponding  $Z$  is 3,244. This gives  $\log. B' = 0.0440$  and  $B' = 1.107$ , whence

$$\tan. \omega = 1.107 \tan. 25^\circ = 0.5162$$

Since  $\tan. 30^\circ = 0.5773$ , the estimated  $\phi$  was evidently too small and  $\tan. \phi$  should be about

$$\tan. 25^\circ + \frac{0.5773 - 0.5162}{1.12} = 0.4663 + 0.0550 = 0.5213$$

Try  $\phi = 27^\circ 32'$ . Then

$$A = 0.4099, \frac{AV^2}{700^2} = 0.2529, Z = 3,450, \log. B' = 0.0468, \text{ and}$$

$$\tan. \omega = 1.114 (0.5213) = 0.5807.$$

Hence increasing  $Z$  by 206 increased  $\tan. \omega$  by 0.0645, so that the value of  $Z$  for  $\omega = 30^\circ$  must be  $3,450 - \frac{34}{0.45} (206) = 3,439$ , which

corresponds to a range of  $\frac{1}{3} CZ = \frac{1}{3} (2.00) (3,439) = 2,293$  yards.

Allowing a margin of about 100 yards to assure clearing the hill-top, the best distance from which to fire is 2,400 yards.

For this range:—

$$Z = \frac{3X}{C} = 3,600, \text{ and therefore}$$

$$\frac{AV^2}{700^2} = 0.2652, H = 0.2645, \log. B' = 0.0488, \log. \frac{V}{u} = 0.0733, N = 1.088,$$

$$\log. Q = 0.0502, \text{ and } \frac{x_o}{X} = 0.5139.$$

Accordingly:

$$\sin. 2\phi = AC = 0.2652 \frac{(700)^2}{(550)^2} (2.00) = 0.8592, \phi = 29^\circ 37' = \text{angle of departure.}$$

$$y_0 = HX \tan. \phi = 0.2645 (7,200) (0.5685) = 1,082 \text{ feet.}$$

$$x_0 = \left(\frac{x_0}{X}\right) X = 0.5139 (7,200) = 3,700 \text{ feet.}$$

$$\tan. \omega = B' \tan. \phi = 1.119 (0.5685) = 0.6360, \omega = 32^\circ 27' = \text{angle of fall.}$$

$$V_\omega = V \left(\frac{u}{V}\right) \cos. \phi \sec. \omega = 550 \left(\frac{1}{1.184}\right) (0.8693) (1.1851) \\ = 478.5 \text{ feet per second} = \text{striking velocity.}$$

$$T = \frac{NX \sec. \phi}{V} = \frac{1.088 (7,200) (1.1503)}{550} \\ = 16.39 \text{ seconds} = \text{time of flight.}$$

$Q$  is here useful only as a check:

$$Q = \frac{V^2 \sin. 2\phi}{gX} = \frac{(550)^2 (0.8592)}{32.16 (7200)} = 1.122 + \text{ and } \log. Q = 0.0502, \text{ which agrees with the tabular value.}$$

7. Table I may be used for any computation for which Table II or IIA is used, though the calculation is more laborious and involves more trial and error computations. When  $Z > 20,000$ , Table I must be used.

Suppose it is desired to find the range of the 3-inch 15-pounder R. F. gun, knowing  $V = 2,600$ ,  $i = 0.90$ ,  $\phi = 42^\circ$ .

$$\text{Compute } C = \frac{w}{\beta i d^2} f_a = \frac{15}{\sqrt{\sec. 42^\circ} (0.9) (9)} f_a = 1.598 f_a.$$

To avoid unnecessary recomputation a preliminary estimate of  $f_a$  should be made, thus enabling the second trial value of  $C$  to be made exact.  $f_a$  will here be estimated as 1.25.

$$C = 1.25 (1.598) = 1.998, \text{ say } 2.00.$$

$$A = \frac{\sin. 2\phi}{C} = \frac{\sin. 84^\circ}{2} = 0.49726.$$

This is within the limits of Table II, but Table I will first be used to solve the problem. From (7), since  $y = 0$  at the point of fall,

$$\tan. \phi = \frac{C}{2 \cos.^2 \phi} \left( \frac{A_u - A_v}{S_u - S_v} - I_v \right)$$

or

$$\frac{\sin. 2\phi}{C} = A \text{ of Table II, } = 0.49726 = \left( \frac{A_u - A_v}{S_u - S_v} - I_v \right)$$

In Table I, for  $V = 2,600$ , one finds:

$$S_v = 2,967.1, A_v = 120.36, I_v = 0.05197, \text{ and } T_v = 0.970$$

so that, by the above equation,  $A_u = 0.54923 (S_u - 2967.1) + 120.36$ .

$u$  must now be found by trial. Try  $u = 600$ .

$S_u = 21,638.7$ ,  $A_u = 9,633.68$ . Hence

trial  $A_u = 0.54923 (18,671.6) + 120.36 = 10,375.2 > 9,633.7$ .

Therefore 600 was too large. Try  $u = 560$ .

$S_u = 23,114.1$ ,  $A_u = 12,036.9$ , and

trial  $A_u = 0.54923 (20,147.0) + 120.36 = 11,185.6 < 12,036.9$ .

When  $u = 600$ , the computed  $A_u$  was too large by 741.5.

When  $u = 560$ , the computed  $A_u$  was too small by 851.3.

Hence true value of  $u = 600 - \left( \frac{741.5}{741.5 + 851.3} \right) (40) = 581.4$ .

Corresponding value of  $T_u$  is 21.322.

Hence from (9),  $T = C \sec. \phi (T_u - T_v)$

$$= 2(1.3456) (21.322 - 0.970) = 54.78 \text{ seconds.}$$

And by (11)  $y_o = 4.05 T^2 = 12,150$  feet.

Therefore the mean height  $= 0.62(12,150) = 7,540$  feet and  $f_a = 1.257$ , so that true value of  $C = 1.257(1.598) = 2.020$ .

A recomputation should now be made and more accurate interpolation made.

$$\frac{\sin. 2\phi}{C} = 0.49234 = \left( \frac{A_u - 120.4}{S_u - 2,967} \right) - 0.05197, \text{ and}$$

$$0.54431(S_u - 2,967) + 120.4 = A_u.$$

Try  $u = 580$ :  $S_u = 22,364$  and  $A_u = 10,762.5$ .

$$0.54431(22,364 - 2,967) + 120.4 = 10,678.4 = A_u - 84.1.$$

Try  $u = 583$ :  $S_u = 22,253$  and  $A_u = 10,584.4$ .

$$0.54431 (22,253 - 2,967) + 120.4 = 10,617.9 = A_u + 33.5.$$

Therefore true  $u = 580 + \frac{84.1}{84.1 + 33.5} (3) = 582.15$  foot-seconds.

The corresponding primary functions are:

$$S_u = 22,285, A_u = 10,634.6, I_u = 1.60976, T_u = 21.275.$$

Hence by

$$(6), X = C (S_u - S_v) = 2.020 (22,285 - 2,967) = 39,030 \text{ feet} = 13,010 \text{ yards.}$$

$$\begin{aligned} (8), \tan. \theta &= \tan. \phi - \frac{C}{2 \cos.^2 \phi} (I_u - I_v) \\ &= 0.90040 - \frac{2.020}{2(0.74314)^2} (1.60976 - 0.05197) \\ &= -1.9496 \end{aligned}$$

$$\text{or } \omega = \tan.^{-1} 1.9496 = 62^\circ 51' = \text{angle of fall.}$$

$$(9), T = C \sec. \phi (T_u - T_v)$$

$$= 2.020 (1.3456) (21.275 - 0.970) = 54.95 \text{ seconds.}$$

$$(10) V\omega = u \frac{\sec. \omega}{\sec. \phi} = (582.15) \frac{(2.1914)}{(1.3456)} = 948.3 \text{ foot-seconds.}$$

$$(11) y_o = 4.05 T^2 = 12,210 \text{ feet.}$$

The computation by Table II is much shorter. Taking  $C=2.020$  as just determined,

$$A = \frac{\sin. 2\phi}{C} = 0.49234, \text{ whence } Z = 19,318, \text{ corresponding to } V = 2,600.$$

Thence

$$H = 0.39109, \log. B' = 0.33530, u = 582.2, T = 20.306$$

and  $X = (19,318) (2.020) = 39,030 \text{ feet} = 13,010 \text{ yards.}$

$$y_0 = 0.39109 (39,030) (90,040) = 13,740 \text{ feet.}$$

$$\tan \omega = 2.164 (9,004) = 1.949, \omega = 62^\circ 50'.$$

$$V_\omega = 582 \frac{(2.191)}{(1.3456)} = 948 \text{ foot-seconds.}$$

$$T = 2.020 (1.3456) (20.306) = 54.95 \text{ seconds.}$$

The results by the two methods are seen to agree precisely except for the maximum ordinate. The labor of finding accurately  $y_0$  by Table I is so great that it is customary to use the approximate formula (11) derived from the equations in vacuo. It is seen that (11) gives too low values for  $y_0$  when  $\phi$  is large.

8. Table IIA is intended to be used for the computation of any high-angle fire trajectory in which the initial velocity is below about 1,000 foot-seconds, since the velocity falls to a small fraction of its initial value at the summit and the quadratic law of air resistance applies throughout except for a small portion of the ascending branch.

Calculate the range, time of flight, etc., for the 12-inch steel mortar, firing an 800-pound steel shell (2-caliber ogive) at an elevation of  $53^\circ 11'$  with a muzzle velocity of 980 foot-seconds.

Compute C.

$$i = 1, \beta = \sqrt{\sec. 53^\circ 11'} = 1.292, w = 800, d = 12, \frac{\delta_1}{\delta} = 1, f_w = 1, \text{ so that}$$

$$C = f_w f_a \frac{\delta_1}{\delta} \frac{w}{\beta i d^2} = \frac{(800) f_a}{(1.292)(144)} = 4.30 f_a.$$

To enter the table, calculate  $\frac{A V^2}{700^2}$ , neglecting  $f_a$  for the time being.

$$\frac{A V^2}{700^2} = \frac{V^2}{700^2} \left( \frac{\sin. 2\phi}{C} \right) = \left( \frac{980}{700} \right)^2 \left( \frac{0.9604}{4.30} \right) = 0.4380$$

In Table IIA the corresponding value of  $Z$  is 5,575, and of  $H$  is 0.2728, whence

$$X = CZ = 24,000 \text{ feet, or } 8,000 \text{ yards}$$

$$\text{and } y_0 = HX \tan. \phi = 0.2728 (24,000) (1.335) = 8,740 \text{ feet,}$$

$$\text{whence } \log. f_a = 8,740 \times 10^{-5} = 0.0874 \text{ and } f_a = 1.22 \text{ by (5).}$$

Recomputing:

$$C = 4.30 f_a = (4.30) (1.22) = 5.25$$

$$\frac{AV^2}{700^2} = \left(\frac{980}{700}\right)^2 \left(\frac{0.9604}{5.25}\right) = 0.3585, \text{ and therefore}$$

$$Z = 4,691, H = 0.2691, \log. B' = 0.0637, \log. \frac{V}{u} = 0.0957, N = 1.117,$$

$$\text{and } \frac{x_o}{X} = 0.5183.$$

The results are then—

$$X = CZ = (5.25) (4,691) = 24,600 \text{ feet} = 8,200 \text{ yards.}$$

$$y_o = (0.2691) (24,600) (1.335) = 8,840 \text{ feet.}$$

$$\tan. \omega = B' \tan. \phi = 1.157 (1.335) = 1.543.$$

$$\omega = \tan.^{-1} 1.543 = 57^\circ 4'.$$

$$u = \left(\frac{u}{V}\right) V = \frac{980}{1.248} = 785.$$

$$V_\omega = u \cos. \phi \sec. \omega = (785) (0.599) (1.843) = 867 \text{ foot-seconds.}$$

$$T = \frac{NX \sec. \phi}{V} = \frac{1.117 (24,600) (1.670)}{980} = 46.7 \text{ seconds.}$$

$$x_o = 0.5183 (24,600) = 12,720 \text{ feet} = 4,240 \text{ yards.}$$

The range table gives  $X = 8,000$  yards and  $T = 46.6$  seconds. Since the first value of  $X$ , computed with  $f_a = 1$ , was just 8,000 yards, it appears that the firings upon which this range table was based determined the reducing factor  $\gamma$  to be 1.22 at this elevation. It is to be noted that a change of 22 per cent in  $C$  caused a change of only 2.7 per cent in range. This brings out the characteristic feature of mortar fire; that the usual service trajectories approximate quite nearly to trajectories in a vacuum.

Problems in accuracy of fire are very important, and two examples are given. The fundamental definitions used in probability of fire are:

(a) The mean error of a gun is the mean distance from a point of fall to the center of impact of several consecutive rounds.

(b) The probable error is that error which it is equally likely will be exceeded or will not be exceeded by any single deviation. It is 0.846 times the mean error. The 50 per cent zone, containing half the hits, has a width twice the probable error or 1.69 times the mean error.

(c) The resultant error in any quantity due to several independent causes is the square root of the sum of the squares of the independent errors.

9. Ten consecutive rounds fired with the 3-inch 15-pounder, long-pointed shell, at  $15^\circ$  elevation,  $V=2,596$ , gave the following results:

Mean range = 11,339 yards.

Mean deviation in range = 109 yards.

Mean deflection = 169 yards to the right.

Mean deviation in deflection = 19 yards.

(a) What are the widths of the 50 per cent zones for range and deflection?

(b) What is the chance of hitting a vertical target 20 yards square at this range?

(a) The mean error in range was 109 yards, so that the 50 per cent zone for range is  $1.69 (109) = 184$  yards wide.

Similarly the mean error in deflection being 19 yards, the 50 per cent zone for deflection is  $1.69 (19) = 32$  yards wide.

(b) The vertical error must be found from the error in range by (25).

First  $\omega$  must be found. Since  $\phi = 15^\circ$ ,  $V = 2,596$ ,  $X = 34,017$ ,

$$\log. Q = \log. \frac{V^2 \sin. 2\phi}{gx} = 0.48855.$$

From Table II, the corresponding  $Z$  is 11,475 and  $\log. B'$  is 0.29877. Hence  $\tan \omega = B' \tan \phi = 1.9896 \tan 15^\circ = 0.5332$ , and  $\omega = 28^\circ 4'$ . Substituting in (25)

$$\Delta X = \frac{h}{0.5332} \left( 1 + \frac{h}{0.533 (34,000)} \right) = 1.87h \left( 1 + \frac{h}{18,100} \right)$$

so that a targets 20 yards high is equivalent to a horizontal target of length  $\Delta X = 1.878(60) \left( 1 + \frac{60}{18,100} \right) = 113$  feet = 38 yards.

In Table VIII,  $\frac{Z}{Z_1}$ , the ratio of the width of a zone containing  $a$  per cent of the shots to the width of the 50 per cent zone, is tabulated against  $a$ .

In this case the vertical target represents a zone for deflection of width  $\frac{20}{32}$  or 62.5 per cent of the 50 per cent zone, and a zone for range of width  $\frac{38}{184}$  or 20.6 per cent of the 50 per cent zone.

In Table VIII for  $\frac{Z}{Z_1} = 0.625$ , the per cent  $a$  is 32.7, and for  $\frac{Z}{Z_1} = 0.206$   $a$  is 11.3.

Therefore the fraction of all the shots hitting the target is  $0.327 \times 0.113 = 0.037$  and the chance of hitting the target is only 3.7 in a hundred.

10. The mean variation in velocity for the 10 rounds of example 9 was 14.4 foot-seconds.

What was the mean error in range caused by this variation in velocity? And what variation in jump would be necessary to account for the remainder of the observed mean deviation in range?

In example 9, the value of  $Z$  for the trajectory was found to be 14,475. For this value of  $Z$ , and

$$V=2,500, A \text{ is } 0.17985$$

$$V=2,596, A \text{ is } 0.16868$$

$$V=2,700, A \text{ is } 0.15741$$

Therefore the mean value of  $\Delta A_v$  for a change of  $\Delta V$  in  $V$  is:

$$\Delta A_v = -(0.02244) \frac{\Delta V}{200} = -0.000112 \Delta V$$

From formula (30), the per cent change in range caused by a change of  $\Delta V$  in  $V$  is:

$$\frac{\Delta X}{X} = -\frac{L \Delta A_v}{A},$$

Substituting for  $L$  (from example 9) and  $\frac{\Delta A_v}{A}$ ,

$$\frac{\Delta X}{X} = \frac{-1}{1.9896} \left( -\frac{0.000112 \Delta V}{0.16868} \right) = 0.000335 \Delta V$$

Therefore a mean variation of 14.4 foot-seconds in  $V$  results in a mean variation in range of

$$\Delta X = (11,339) (0.000335) (14.4) = 54.6 \text{ yards.}$$

The observed mean deviation in range was 109 yards so that the mean variation due to other causes than velocity is

$$\sqrt{109^2 - 55^2} = 94 \text{ yards.}$$

Referring again to formula (30) the per cent change in range due to a change of  $\Delta \phi$  minutes in  $\phi$  is

$$\frac{\Delta X}{X} = \frac{L}{1,719} \frac{\Delta \phi}{\tan. 2\phi}$$

Here  $\phi = 15^\circ$ ,  $L = \frac{1}{1.9896}$ , so that

$$\Delta X = \left( \frac{11,339}{1,719} \right) \left( \frac{1}{1.9896} \right) \left( \frac{\Delta \phi}{0.5773} \right) = 5.75 \Delta \phi \text{ yards.}$$

In order to cause a mean error of 94 yards, the mean variation in  $\phi$  would have to be  $\frac{94}{5.75} = 16$  minutes. Evidently therefore the portion of the 94-yard residual error to be ascribed to  $\phi$  is small. A mean variation in  $\phi$  of about 2 minutes is a reasonable value to assume. This would leave a residual error of

$$\sqrt{94^2 - 12^2} = 93 \text{ yards}$$

which must be ascribed to varying degrees of steadiness in flight, varying air currents encountered, etc. From formula (30) again:

$$\frac{\Delta X}{X} = + (1-L) \frac{\Delta C}{C} = \frac{93}{11,339} = + \frac{0.9896}{1.9896} \frac{\Delta C}{C}$$

or  $\frac{\Delta C}{C} = 0.0165$

Therefore a mean variation of 1.6 per cent in the density of the air encountered would have caused the same error as the observed variations in flight conditions did. Hence it is seen that (considering the attendant changes in M. V.) a mean variation from round to round of 1 per cent in the weight of projectile would hardly have affected the accuracy of this gun *at this particular range*.

TABLE IIA. *Quadratic law.*[ $V=0$  to  $V=825$ .]

A modified form of Table II for use with initial velocities between 0 and 825 f. s. The  $A$  column is computed for  $V=700$  f. s. To find  $A$  for any other initial velocity  $V$ , multiply the tabular value by  $(\frac{700}{V})^2$ .  $U$  is replaced by  $\log \frac{V}{u}$  and  $T'$  is replaced by  $N = \frac{VT'}{Z}$  in order to make the tabular values independent of  $V$ . The other functions are the same as in Table II.

$Z = \frac{X}{C}$	$\frac{AV^2}{700^2}$	$\Delta$	$H$	$\Delta$	$\log B'$	$\Delta$	$\log \frac{V}{u}$	$\Delta$	$N$	$\Delta$	$\log Q$	$\Delta$	$\frac{x_0}{X}$	$\Delta$

80	+.0101	20	23	25
90	+.0228	46	52	58
100	+.0387	77	87	96

Computed from the formula

$$\frac{\Delta V}{V} = .00867 (2^{.032t} - 2^{.032 \times 70}).$$

$$= .00867 (2^{.032t} - 4.73).$$

TABLE VIII. *A probability table showing the ratio of the expected width Z of the zone containing a certain percentage of shots to the width Z<sub>1</sub> of the 50 per cent zone. Thus, if 41 per cent of the shots are observed to fall within a zone 100 yards wide, 50 per cent of the shots should have fallen in a zone  $\frac{100}{.80}$  or 125 yards wide.*[Values of Z/Z<sub>1</sub>.]

TABLE IX. *Curvature of the earth.*

$$K = [3.3333 - 10] \quad R^2 = 2154 \left( \frac{R}{1000} \right)^2$$

In which  $K$  is the curvature in feet and  $R$  the range in yards. The curvatures in feet for ranges at 1,000 yards interval are given in the following table:

Range.	Curvature.	$\Delta$	Range.	Curvature.	$\Delta$
<i>Yards.</i>	<i>Feet.</i>	<i>Feet.</i>	<i>Yards.</i>	<i>Feet.</i>	<i>Feet.</i>
1,000	0.22	0.64	19,000	77.8	8.4
2,000	0.86	1.08	20,000	86.2	8.8
3,000	1.94	1.51	21,000	95.0	9.3
4,000	3.45	1.94	22,000	104.3	9.7
5,000	5.39	2.36	23,000	114.0	10.1
6,000	7.75	2.80	24,000	124.1	10.5
7,000	10.55	3.24	25,000	134.6	11.0
8,000	13.79	3.66	26,000	145.6	11.4
9,000	17.45	4.09	27,000	157.0	11.9
10,000	21.54	4.52	28,000	168.9	12.3
11,000	26.06	4.96	29,000	181.2	12.7
12,000	31.02	5.38	30,000	193.9	13.1
13,000	36.40	5.82	31,000	207.0	13.6
14,000	42.22	6.25	32,000	220.6	14.0
15,000	48.47	6.67	33,000	234.6	14.4
16,000	55.14	7.11	34,000	249.0	14.9
17,000	62.25	7.54	35,000	263.9	15.3
18,000	69.79	7.97	36,000	279.2	

TABLE X. *The Altitude Factor.**Ratio of air density at sea level to the density at any height above sea level.*[Computed from the formula:  $f_a = (1 - .0000064h)^{-4.868}$ .]

<i>h</i>	<i>f<sub>a</sub></i>	$\Delta$	<i>h</i>	<i>f<sub>a</sub></i>	$\Delta$
<i>Feet.</i>			<i>Feet.</i>
